Two-Task Competition in Low-Rank RNNs

```
Full Experiment Report
Generated 2026-03-20 12:52:39

Parameters:
  N = 500   |   n_seeds = 5   |   t_max = 100.0
  dt = 0.05  |   seed = 42          |   D_mean = 2.5

Contents:
  Families  — Multi-seed deep-dives for all three blueprint families
    1. Frequency (ω):  S vs Δω, sensitivity dS/dΔω vs D_mean
    2. Amplitude (γ):  S vs Δγ, sensitivity dS/dΔγ vs D_mean
    3. Shape (ε):      S vs Δε, sensitivity dS/dΔε vs D_mean

  Comparison — Cross-regime experiments
    LC freq, FP rotation, FP coupling, cross-comparison
    Seed-averaged heatmaps for Δω and Δb
```

Families 1–3: Multi-Seed Deep-Dives

```
For each of the three blueprint families:

  Family 1 — Frequency:   A(ω) = 0.8 [[1, ω], [-ω, 1]],       base ω = 0.5
  Family 2 — Amplitude:   A(γ) = γ   [[1, 0.5], [-0.5, 1]],    base γ = 0.8
  Family 3 — Shape:       A(ε) = 0.8 [[ε, 0.5], [-0.5, 1/ε]],  base ε = 1.0

Two analyses per family (multi-seed averaged):
  1. S vs Δ(feature) at several fixed ΔD values, with ±1σ bands
     Right panel: ΔD = 0 only — does feature difference alone
     drive winner-take-all?
  2. Sensitivity dS/d(Δfeature) at Δfeature = 0 as a function
     of mean connection strength D_mean
```

Comparison Experiments

```
Cross-regime experiments and averaged heatmaps:

  Exp 1  — LC frequency competition (varying Δω)
  Exp 2a — FP rotation (varying eigenvector angle θ)
  Exp 2b — FP coupling (varying off-diagonal Δb)
  Exp 3  — Cross-comparison (LC-vs-LC, FP-vs-FP, Mixed)

  Averaged heatmaps of S(Δfeature, ΔD) for Δω and Δb
  S at ΔD = 0, sensitivity slopes at zero feature gap
```
